Abstract

A combined nonlinear longitudinal and lateral vehicle control is investigated. Flatness-based nonlinear control and new algebraic estimation techniques for noise removal and numerical differentiation are the main theoretical tools. An accurate automatic path-tracking via vehicle steering angle and driving/braking wheel torque is thus ensured. It combines the control of the lateral and longitudinal motions in order to track straight or curved trajectories and to perform a combined lane-keeping and steering control during critical driving situations such as obstacle avoidance, stop-and-go control, lane-change maneuvers or any other maneuvers. Promising results have been obtained with noisy experimental data, which were acquired by a laboratory vehicle with high dynamic loads and high lateral accelerations.

Keywords: Intelligent transportation systems, coupled longitudinal/lateral vehicle control, flatness-based control, estimation, noise removal, numerical differentiation, algebraic techniques.

1. Introduction

The development and integration of intelligent systems for autonomous vehicles have received a lot of attention during the last decades. The aim of such systems is to reduce the driver's physical and mental workload (Tanaka et al., 2000). They have also been introduced to help the driver to cope with critical driving situations and make the vehicle more stable and steerable. A considerable effort has been achieved in order to develop several active and passive assistance systems, like Anti-Lock Braking System (ABS), Electronic Stability Program (ESP), Adaptive Cruise Control (ACC) and recently four wheel steering systems.

Vehicle dynamic control (VDC) has been widely discussed in the literature. Particularly, several studies on longitudinal and lateral control have been conducted and published. A major part of them deals with longitudinal or lateral control separately but rarely with a coupled one. Unfortunately, many critical driving situations involving the safe handling of vehicles require coupled control, and, such a strategy is rarely addressed in already published works. This remark is emphasized in surveys (Nobe & Wang, 2001; Khodayari et al., 2010), where the authors give two lists of works concerning longitudinal and lateral

controllers, and point out that the longitudinal and the lateral controllers are addressed separately in the majority of cases.

Recently, a great many intelligent systems based controllers have been developed via lateral or longitudinal controllers. For lane keeping, lane-change maneuvers, pedestrian and obstacle avoidance, a lateral control is used (see, for example, Ackermann et al. (1995); Guldner et al. (1999); Tomizuka et al. (1999); Rajamani et al. (2000); Hatipoglu et al. (2003); Zheng et al. (2006); Plöchl & Edelmann (2007); Cerone et al. (2009); Marino & Cinili (2009); Menhour et al. (201); Fernandez-Llorca et al. (2011)). While, for stop-and-go, adaptive cruise control and platooning tasks, the longitudinal control is developed (see for example Rajamani et al. (2000); Mammar & Netto (2004); Martinez & Canudas-de-Wit (2007); Nouvelière & Mammar (2007); Villagra et al. (2009)). In (d'Andréa-Novel & Ellouze, 2001; Chou & d'Andréa-Novel, 2005), a nonlinear global chassis controller is proposed which uses braking torques but without active steering control to follow desired trajectories in yaw rate and in longitudinal acceleration. In contrast, some works have dealt with the problem of comfort and improvements of ground vehicle handling through the joint braking and suspension control (see, for example, Poussot-Vassal et al. (2011)). Another approach that combines braking and steering control is also proposed in (Poussot-Vassal et al., 2011), where the longitudinal motion is considered as a varying parameter, and not as a state variable. See also (Zheng et al., 2006) for a similar approach.

Our study proposes a combined vehicle control scheme to cope with driving situations involving high longitudinal speeds

and coupled longitudinal/lateral maneuvers. In fact, in (Mammar & Netto, 2004; Nouvelière & Mammar, 2007), the authors consider an integration of longitudinal and lateral controllers based on second order sliding mode control for vehicle low speed automation. In (Rajamani et al., 2000), a control law for the platooning maneuver is developed via an integration of a longitudinal and a lateral controllers based on H∞ approach and gain-scheduling scheme respectively. For more details on these points, we refer the reader to the surveys due to Nobe & Wang (2001); Plöchl & Edelmann (2007); Khodayari et al. (2010).

Our vehicle control design rests on

1. flatness-based nonlinear control (Fliess et al., 1995, 1999) (see also Fuchshumer et al. (2005) for a related approach);
2. algebraic estimation and identification techniques (Fliess et al., 2008).

A 3DoF nonlinear vehicle model is also considered in order to establish such a controller. The algebraic techniques provide a good estimation of noisy signals derivatives, and are useful because sensors used in a real automotive application are generally low cost and their measurements are very noisy. Hence it is not easy to use such data in control applications.

The remainder of this paper is organized as follows. In the next Section, the flatness-based coupled nonlinear vehicle control problem is addressed. Section 3 presents a 3DoF and a 10DoF nonlinear vehicle model. Both models are respectively used for control design and performance tests. The vehicle coupling effects are also given in Section 3. Section 4 describes the control design steps and the proof of flatness. A short summary of the algebraic techniques and their application for the implementation of control law are given in Section 5. Section 6 presents simulation results using the noisy data acquired on actual roads under high longitudinal speeds and lateral accelerations. Conclusions and perspectives are found in Section 7.

See (Menhour et al., 2011, 2012) for a first draft of this paper.

2. Problem statement

The design and implementation of the coupled longitudinal and lateral vehicle control is one of the most challenging problems in the development of intelligent transportation systems. Such a controller plays a crucial role to carry out coupled maneuvers like automatic driving operations, pedestrian or/and collision avoidance system, lane-change maneuvers, lane keeping. For these reasons, this work deals with the design of a coupled nonlinear vehicle control in two steps:

- **Step 1**: derivatives and filtering of flat outputs using algebraic estimation;

- **Step 2**: flatness-based coupled nonlinear longitudinal and lateral vehicle control;

using the following theoretical tools:

- flatness property of a three degrees-of-freedom two wheels nonlinear vehicle model: flat outputs and the corresponding proof are detailed in Section 4;

- algebraic estimation techniques for denoising and numerical differentiation and their application for filtering and derivatives of flat outputs are given in Section 5.

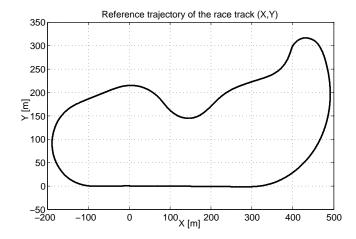

Figure 2: Reference trajectory of the race track

The main objective is achieved via a good choice of flat outputs. With such outputs, the flatness property of (1) is established, since, the nonlinear flat controller is designed. The scheme of Figure 1 shows the design steps and the interaction between them. The first step describes the computing of the reference flat outputs with real data and their derivatives. The used data, have been recorded with an instrumented vehicle during experiments realized on a race track with a professional driver. Then, the obtained trajectory is shown in Figure 2.

3. Vehicle models and coupled dynamic analysis

Two nonlinear vehicle models are used: the first one is a 3DoF NonLinear Two Wheels Model (*3DoF-NLTWVM*) which will be used to design a combined nonlinear control law. The second one is a 10DoF NonLinear Four Wheels Model (*10DoF-NLFWVM*) which will be used in a complete vehicle simulator to test the proposed control law under various driving conditions. In the sequel, we present these models and the reasons for which the coupled nonlinear models are considered.

3.1. 10DoF NonLinear Four Wheels Vehicle Simulation Model

To perform some tests and evaluate the performance of combined controllers, a NonLinear Four Wheels Vehicle Model should be considered. This model is composed from: translational motions (longitudinal x, lateral y and vertical z), rotational motions (roll ϕ, pitch θ and yaw ϕ) and wheels dynamics rotation motions (see Tables A.1 and A.2 for notations). All motions of the model are given in Appendix A.

3.2. 3DoF Nonlinear Two Wheels Vehicle Control Model

The 3DoF Nonlinear Two Wheels Vehicle Control Model (3DoF-NLTWVM) of Figure 3, provides a sufficient approximation of the longitudinal and lateral dynamics of the vehicle. It is used to design a combined controller and composed of the
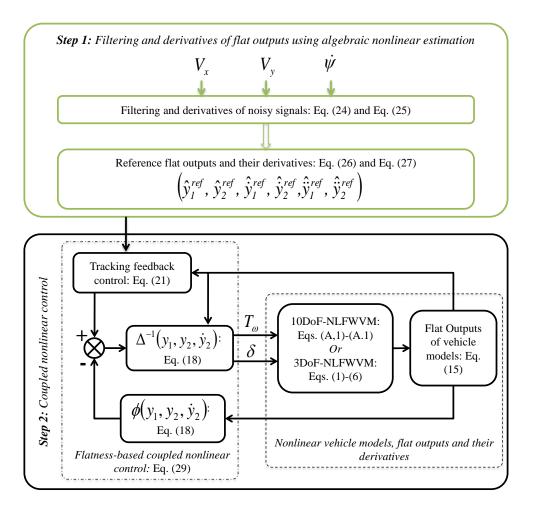

Figure 1: Interaction between the algebraic estimation and flatness-based coupled nonlinear control

longitudinal V_x, lateral V_y and yaw $\dot{\psi}$ motions (see tables A.1 and A.2 for notations). Its equations are:

$$\begin{cases} ma_x = m(\dot{V}_x - \dot{\psi}V_y) = (F_{x1} + F_{x2}) \\ ma_y = m(\dot{V}_y + \dot{\psi}V_x) = (F_{y1} + F_{y2}) \\ I_z\ddot{\psi} = M_{z1} + M_{z2} \end{cases} \quad (1)$$

The forces and moments of Eq. (1) in the vehicle coordinates taking into account the kinetics coupling are:

$$\begin{cases} F_{x1} = F_{xf}\cos(\delta) - F_{yf}\sin(\delta) \\ F_{x2} = F_{xr} \\ F_{y1} = F_{xf}\sin(\delta) + F_{yf}\cos(\delta) \\ F_{y2} = F_{yr} \\ M_{z1} = L_1(F_{yf}\cos(\delta) + F_{xf}\sin(\delta)) \\ M_{z2} = -L_2 F_{yr} \end{cases} \quad (2)$$

Considering small steering angles assumption, the forces and moments, in Eq. (2) become

$$\begin{cases} F_{x1} = F_{xf} - F_{yf}\delta, \ \ F_{x2} = F_{xr} \\ F_{y1} = F_{xf}\delta + F_{yf}, \ \ F_{y2} = F_{yr} \\ M_{z1} = L_1(F_{yf} + F_{xf}\delta), \ \ M_{z2} = -L_2 F_{yr} \end{cases} \quad (3)$$

In Eq. (1) the longitudinal forces are calculated using the dynamical model of the wheels. For the front wheel:

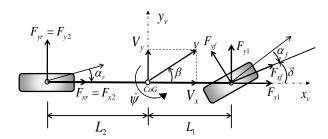

Figure 3: Nonlinear two wheeled vehicle model

$$F_{xf} = (1/R)(-I_\omega\dot{\omega}_f + T_m - T_{bf}) \quad (4)$$

Considering that the vehicle is only propelled by the front wheel, the dynamical model of the rear wheel is as follows:

$$F_{xr} = -(1/R)(T_{br} + I_\omega\dot{\omega}_r) \quad (5)$$

The wheels rotations ω_f and ω_r are assumed to be measured through odometers. They are introduced as external inputs in the equations of the 3DoF-NLTWVM. For our simulations, we assume that the rear braking torque T_{br} can be expressed as proportional to the front braking torque T_{bf}, then, $T_{br} = rT_{bf}$

3

where $0 \leq r \leq 1$ is a repartition braking coefficient between front and rear wheels. The wheels rotation accelerations will be estimated using the algebraic estimation and the measured rotation speeds which are available on the vehicle's CAN bus. Note that we have considered lateral tyre forces to be proportional to the sideslip angles of each axle. The front and rear forces ($F_{yf} = C_f\alpha_f$, $F_{yr} = C_r\alpha_r$) are defined as follows:

$$\begin{cases} F_{yf} = C_f\left(\delta - \frac{V_y + \dot{\psi}L_1}{V_x}\right) \\ F_{yr} = -C_r\left(\frac{V_y - \dot{\psi}L_2}{V_x}\right) \end{cases} \qquad (6)$$

where C_f and C_r are the cornering stiffness cofficients for the front and rear tyres respectively. The longitudinal speed is considered different from zero ($V_x > \varepsilon$). Replacing Eqs. (3), (4), (5) and (6) in Eq. (1) yields:

$$\begin{cases} m\dot{V}_x = m\dot{\psi}V_y - \frac{I_\omega}{R}(\dot{\omega}_r + \dot{\omega}_f) + \frac{1}{R}(T_m - T_{bf} - T_{br}) \\ \qquad + C_f\left(\frac{V_y + L_1\dot{\psi}}{V_x}\right)\delta - C_f\delta^2 \\ m\dot{V}_y = -m\dot{\psi}V_x - C_f\left(\frac{V_y + L_1\dot{\psi}}{V_x}\right) - C_r\left(\frac{V_y - \dot{\psi}L_2}{V_x}\right) \\ \qquad + (1/R)(T_m - T_{bf})\delta + \left(C_f - \frac{I_\omega}{R}\dot{\omega}_f\right)\delta \\ I_z\ddot{\psi} = -L_1 C_f\left(\frac{V_y + L_1\dot{\psi}}{V_x}\right) + L_2 C_r\left(\frac{V_y - L_2\dot{\psi}}{V_x}\right) \\ \qquad + (L_1/R)(T_m - T_{bf})\delta + L_1\left(T_m - \frac{I_\omega}{R}\dot{\omega}_f\right)\delta \end{cases} \qquad (7)$$

The longitudinal movement is controlled via the driving/braking wheel torque $T_\omega = T_m - T_b$ with $T_b = T_{bf} + T_{br}$, and the lateral movement via the steering angle δ. Let us denote the two control variables:

$$\begin{cases} u_1 = T_\omega \\ u_2 = \delta \end{cases} \qquad (8)$$

The model given by Eq. (7) may now be written as follows:

$$\dot{x} = f(x,t) + g(x)u + g_1 u_1 u_2 + g_2 u_2^2 \qquad (9)$$

where:

$$f(x,t) = \begin{bmatrix} \dot{\psi}V_y - \frac{I_\omega}{mR}(\dot{\omega}_r + \dot{\omega}_f) \\ -\dot{\psi}V_x + \frac{1}{m}\left(-C_f\left(\frac{V_y + L_1\dot{\psi}}{V_x}\right) - C_r\left(\frac{V_y - L_2\dot{\psi}}{V_x}\right)\right) \\ \frac{1}{I_z}\left(-L_1 C_f\left(\frac{V_y + L_1\dot{\psi}}{V_x}\right) + L_2 C_r\left(\frac{V_y - L_2\dot{\psi}}{V_x}\right)\right) \end{bmatrix},$$

$$g(x,t) = \begin{bmatrix} \frac{1}{mR} & \frac{C_f}{m}\left(\frac{V_y + L_1\dot{\psi}}{V_x}\right) \\ 0 & (C_f R - I_\omega \dot{\omega}_f)/mR \\ 0 & (L_1 C_f R - L_1 I_\omega \dot{\omega}_f)/I_z R \end{bmatrix}, g_1 = \begin{bmatrix} 0 \\ \frac{1}{mR} \\ \frac{L_1}{I_z R} \end{bmatrix},$$

$$g_2 = \begin{bmatrix} \frac{-C_f}{m} \\ 0 \\ 0 \end{bmatrix}^T, x = \begin{bmatrix} V_x \\ V_y \\ \dot{\psi} \end{bmatrix}^T, u = \begin{bmatrix} u_1 \\ u_2 \end{bmatrix}$$

Remark 1. As mentioned previously, to ensure an efficient control and perform coupled driving maneuvers, a combined lateral/longitudinal controller is required. The design of such a controller requires coupled vehicle models. The vehicle models (A.1) and (1) satisfy these requirements, which include the following coupling effects:

- **Kinematic coupling**: We give a brief description of the kinematic relationship between the vehicle motions like steering and yaw motions. When the vehicle wheels are steered, the longitudinal and lateral forces are functions of the wheel forces and steering angle (see Eqs. (A.4) and (2)). The same reasoning is done for the lateral and the longitudinal displacements, which are also functions of the yaw angle, longitudinal and lateral speeds (see Eq. (A.2)).

- **Load transfer coupling**: The load transfer plays a crucial role in the stability analysis of the vehicle dynamics. This coupling is the consequence of two important points: the first one is related to the road geometry parameters like road bank angle, road slope angle and road curvature, the second one is due mainly to the vehicle dynamics like longitudinal and lateral accelerations, roll and suspension motions. These points change the weight distribution between the front, rear, right and left tyres. Such parameters and motions act strongly on the weight distribution between the vehicle's tyres. All these coupling effects are expressed through the tyre vertical forces model (A.5).

- **Coupling of tyre behavior**: The behavior of the vehicle models strongly depend on tyre-road forces. The coupled tyre models (A.3) represent only the relationship between the road and the vehicle and are required to ensure a realistic behavior of the vehicle. Such a model considers the coupling of longitudinal slip ratio, sideslip angle, vertical forces and camber angle.

4. Flatness-based control

Flatness-based control ((Fliess et al., 1995, 1999) and (Lévine, 2009; Sira-Ramírez & Agrawal, 2004)) has already found numerous engineering applications. See, e.g., for coupled nonlinear vehicles (Fuchshumer et al., 2005; Menhour et al., 2011, 2012) and for underwater vehicles (Rathinam & Murray, 1998). Flatness is demonstrated for a 3DoF nonlinear two wheels vehicle model of the form depicted in (14).

4.1. Flatness property: A short summary

Consider the system

$$\dot{x} = f(x,u) \qquad (10)$$

where $x = (x, \cdots, x_n) \in \mathbb{R}^n$ and $u = (u, \cdots, u_m) \in \mathbb{R}^m$. It is said to be (*differentially*) *flat* (see (Fliess et al., 1995, 1999) and (Sira-Ramírez & Agrawal, 2004; Lévine, 2009)) if, and only if:

- there exists a vector-valued function h such that

$$y = h(x, u, \dot{u}, \cdots, u^{(r)}) \qquad (11)$$

where $y = (y, \cdots, y_m) \in \mathbb{R}^m$, $r \in \mathbb{N}$;

- the components of $x = (x, \cdots, x_n)$ and $u = (u, \cdots, u_m)$ may be expressed as

$$x = A(y, \dot{y}, \cdots, y^{(r_x)}), \quad r_x \in \mathbb{N} \tag{12}$$

$$u = B(y, \dot{y}, \cdots, y^{(r_u)}), \quad r_u \in \mathbb{N} \tag{13}$$

Remember that y in Eq. (11) is called a *flat output*. It is well known that a flat system is equivalent to a linear one via an *endogenous* feedback (Fliess et al., 1995, 1999) and (Lévine, 2009; Sira-Ramírez & Agrawal, 2004).[1]

4.2. Flatness-based longitudinal and lateral control

In order to reduce the complexity of the nonlinear model in Eq. (9), nonlinear terms such as $u_1 u_2$ and u_2^2 are neglected.[2] Despite these simplifications, coupled behaviors are kept as shown by the functions $f(x,t)$ and $g(x,t)$. Eq. (9) becomes:

$$\dot{x} = f(x,t) + g(x,t)u \tag{14}$$

4.2.1. A proof of flatness
PROOF. We want to show that y_1 and y_2 given by

$$\begin{cases} y_1 = V_x \\ y_2 = L_1 m V_y - I_z \dot{\psi} \end{cases} \tag{15}$$

define flat outputs for system (14). Some algebraic manipulations yield

$$\begin{aligned} x &= A(y_1, y_2, \dot{y}_2) \\ &= \begin{bmatrix} y_1 \\ \frac{y_2}{L_1 m} - \left(\frac{I_z}{L_1 m}\right) \left(\frac{L_1 m y_1 \dot{y}_2 + C_r(L_1+L_2)y_2}{C_r(L_1+L_2)(I_z - L_2 L_1 m) + (L_1 m y_1)^2}\right) \\ -\left(\frac{L_1 m y_1 \dot{y}_2 + C_r(L_1+L_2)y_2}{C_r(L_1+L_2)(I_z - L_2 L_1 m) + (L_1 m y_1)^2}\right) \end{bmatrix} \end{aligned} \tag{16}$$

and

$$\begin{bmatrix} \dot{y}_1 \\ \ddot{y}_2 \end{bmatrix} = \Delta(y_1, y_2, \dot{y}_2) \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} + \Phi(y_1, y_2, \dot{y}_2) \tag{17}$$

Then

$$\begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \Delta^{-1}(y_1, y_2, \dot{y}_2) \left(\begin{bmatrix} \dot{y}_1 \\ \ddot{y}_2 \end{bmatrix} - \Phi(y_1, y_2, \dot{y}_2) \right) \tag{18}$$

where

---

[1] An endogenous feedback is a peculiar type of dynamic feedback.
[2] The results of Section 6 fully justify those approximations.

$$\begin{cases} \Delta_{11}(y_1, y_2, \dot{y}_2) &= \frac{1}{mR} \\ \Delta_{12}(y_1, y_2, \dot{y}_2) &= \frac{C_f}{m}\left(\frac{V_y + L_1 \dot{\psi}}{y_1}\right) \\ \Delta_{22}(y_1, y_2, \dot{y}_2) &= \left(\frac{L_2 C_r(L_1+L_2) - L_1 m y_1^2}{y_1}\right)\left(\frac{L_1 C_f R - L_1 I_\omega \dot{\omega}_f}{I_z R}\right) \\ &\quad + \left(\frac{(C_r(L_1+L_2)(V_y - L_2\dot{\psi}) - L_1 m \dot{\psi} y_1^2)}{y_1^2}\right) \times \\ &\quad \left(\frac{C_f(V_y + L_1\dot{\psi})}{my_1}\right) - \left(\frac{C_r(L_1+L_2)}{y_1}\frac{RC_f - I_\omega \dot{\omega}_f}{mR}\right) \\ \Delta_{21}(y_1, y_2, \dot{y}_2) &= \left(\frac{C_r(L_1+L_2)(V_y - L_2\dot{\psi}) - L_1 m \dot{\psi} y_1^2}{mR y_1^2}\right) \end{cases}$$

and

$$\begin{cases} \Phi_1(y_1, y_2, \dot{y}_2) &= \dot{\psi}V_y - \frac{I_\omega}{mR}(\dot{\omega}_r + \dot{\omega}_f) \\ \Phi_2(y_1, y_2, \dot{y}_2) &= -L_1 m y_1 f_3(x,t) - \frac{C_r(L_1+L_2)}{y_1}f_2(x,t) \\ &\quad + \frac{C_r(L_1+L_2)(V_y - L_2\dot{\psi}) - L_1 m \dot{\psi} y_1^2}{y_1^2}f_1(x,t) \\ &\quad + \frac{L_2 C_r(L_1+L_2)}{y_1}f_3(x,t) \end{cases}$$

The flatness property holds therefore if the matrix $\Delta(y_1, y_2, \dot{y}_2)$ is invertible. It reads

$$\begin{aligned} \det(\Delta(y_1, y_2, \dot{y}_2)) &= \Delta_{11}\Delta_{22} - \Delta_{21}\Delta_{12} \\ &= \frac{(I_\omega \dot{\omega}_f - C_f R)(L_1^2 y_1^2 m^2 - C_r(L_1+L_2)L_2 L_1 m + C_r I_z L)}{I_z R^2 y_1 m^2} \neq 0 \end{aligned} \tag{19}$$

This determinant, which depends only on the longitudinal speed $y_1 = V_x$, is indeed nonzero:

- The wheel rotation acceleration is less than RC_f/I_ω: RC_f/I_ω is around 10^4, then $I_\omega \dot{\omega}_f - C_f R \neq 0$.

- Notice that $I_z > L_1 m$, then: $C_r(L_2 + L_1)(I_z - L_1 m) + L_1^2 m^2 y_1^2 \neq 0$.

Thus

$$\begin{cases} u &= B(y_1, \dot{y}_1, y_2, \dot{y}_2, \ddot{y}_2) \\ &= \Delta^{-1}(y_1, y_2, \dot{y}_2)\left(\begin{bmatrix} \dot{y}_1 \\ \ddot{y}_2 \end{bmatrix} - \Phi(y_1, y_2, \dot{y}_2)\right) \end{cases} \tag{20}$$

with $r_x = 1$ and $r_u = 2$ and

$$\begin{bmatrix} \dot{y}_1 \\ \ddot{y}_2 \end{bmatrix} = \begin{bmatrix} \dot{y}_1^{ref} + K_1^1 e_{y_1} + K_1^2 \int e_{y_1} dt \\ \ddot{y}_2^{ref} + K_2^1 e_{y_2} + K_2^2 \int e_{y_2} dt + K_2^3 \dot{e}_{y_2} \end{bmatrix} \tag{21}$$

where, $e_{y_1} = y_1^{ref} - y_1 = V_x^{ref} - V_x$ and $e_{y_2} = y_2^{ref} - y_2$. The gain tuning K_1^1, K_1^2, K_2^1, K_2^2 and K_2^3 is then straightforward thanks to the equivalent with linear systems (see Section 4.1).

5. Algebraic estimation

Measured variables and their derivatives are needed in the control law (21) which is constructed via derivatives of reference outputs. See (Villagra et al., 2009, 2011; Abouaïssa et al., 2012) for previous successful applications to intelligent transportation systems.

5.1. Denoising and numerical derivation: a short summary

Start, for simplicity's sake, with a time signal corresponding to the first degree polynomial time function $p_1(t) = a_0 + a_1 t$, $t \geq 0$, $a_0, a_1 \in \mathbb{R}$. Rewrite, thanks to classic operational calculus (see, e.g., (Yosida, 1984)) p_1 as $P_1 = \frac{a_0}{s} + \frac{a_1}{s^2}$. Multiply both sides by s^2:

$$s^2 P_1 = a_0 s + a_1 \qquad (22)$$

Take the derivative of both sides with respect to s, which corresponds in the time domain to the multiplication by $-t$:

$$s^2 \frac{dP_1}{ds} + 2s P_1 = a_0 \qquad (23)$$

The coefficients a_0, a_1 are obtained via the triangular system of Eqs. (22)-(23). We get rid of the time derivatives, i.e., of sP_1, $s^2 P_1$, and $s^2 \frac{dP_1}{ds}$, by multiplying both sides of Eqs. (22)-(23) by s^{-n}, $n \geq 2$. The corresponding iterated time integrals are low pass filters which attenuate the corrupting noises, viewed as highly fluctuating phenomena (see (Fliess, 2006; Fliess et al., 2008)). A quite short time window is sufficient for obtaining accurate values of a_0, a_1. The extension to polynomial functions of higher degree is straightforward. For derivatives estimates up to some finite order of a given smooth function $f : [0, +\infty) \to \mathbb{R}$, take a suitable truncated Taylor expansion around a given time instant t_0, and apply the previous computations. Resetting and using sliding time windows allow to estimate derivatives of various orders at any sampled time instant.[3] The following formulae may be used in practice and yield straightforward discrete linear filters:

- Denoising:

$$\hat{y}(t) = \frac{2!}{T^2} \int_{t-T}^{t} (2T - 3\tau) y(\tau) d\tau \qquad (24)$$

- Numerical differentiation of a noisy signal:

$$\hat{y}(t) = -\frac{3!}{T^3} \int_{t-T}^{t} (T - 2\tau) y(\tau) d\tau \qquad (25)$$

Note that the sliding time window $[t - T, t]$ may be quite short.

---

[3]See (Fliess et al., 2008; Mboup et al., 2009) for more details.

5.2. Application

- The estimated derivatives $\hat{V}_x^{ref}$, $\hat{V}_y^{ref}$, $\hat{\psi}^{ref}$, $\hat{\omega}_f$ and $\hat{\omega}_r$ are performed as follows:

$$
\begin{bmatrix} \hat{V}_x^{ref} \\ \hat{V}_y^{ref} \\ \hat{\psi}^{ref} \\ \hat{\omega}_f \\ \hat{\omega}_r \end{bmatrix} = -\frac{3!}{T^3} \int_{t-T}^{t} (2T(t-\tau) - T) \begin{bmatrix} V_x^{ref} \\ V_y^{ref} \\ \psi^{ref} \\ \omega_f \\ \omega_r \end{bmatrix} d\tau \quad (26)
$$

- The filtering of $\hat{V}_x^{ref}$, $\hat{V}_y^{ref}$ and $\hat{\psi}^{ref}$ is performed as follows:

$$
\begin{bmatrix} \hat{V}_x^{ref} \\ \hat{V}_y^{ref} \\ \hat{\psi}^{ref} \end{bmatrix} = \frac{2!}{T^2} \int_{t-T}^{t} (3(t-\tau) - T) y(\tau) \begin{bmatrix} V_x^{ref} \\ V_y^{ref} \\ \psi^{ref} \end{bmatrix} d\tau \quad (27)
$$

Then, the flat outputs references are computed using Eqs. (26) and (27) as follows:

$$
\begin{cases}
\hat{y}_1^{ref} = \hat{V}_x^{ref} \\
\dot{\hat{y}}_1^{ref} = \hat{V}_x^{ref} \\
\hat{y}_2^{ref} = L_1 m \hat{V}_y^{ref} - I_z \hat{\psi}^{ref} \\
\dot{\hat{y}}_2^{ref} = L_1 m \hat{V}_y^{ref} - I_z \hat{\psi}^{ref} \\
\ddot{\hat{y}}_2^{ref} = L_1 m \dot{\hat{V}}_y^{ref} - I_z \ddot{\hat{\psi}}^{ref}
\end{cases}
\quad (28)
$$

The tracking errors are:

$$
\begin{cases}
\hat{e}_{y_1} = \hat{y}_1^{ref} - y_1 \\
\hat{e}_{y_2} = \hat{y}_2^{ref} - y_2 \\
\dot{\hat{e}}_{y_2} = \dot{\hat{y}}_2^{ref} - \dot{y}_2
\end{cases}
\quad (29)
$$

The equation of the coupled nonlinear control obtained from Eqs. (20), (21) and (28) reads:

$$
u = \begin{bmatrix} T_\omega \\ \delta \end{bmatrix} = -\Delta^{-1}(y_1, y_2, \dot{y}_2) \Phi(y_1, y_2, \dot{y}_2)
$$
$$
+ \Delta^{-1}(y_1, y_2, \dot{y}_2) \times \begin{bmatrix} \dot{\hat{y}}_1^{ref} + K_1^1 \hat{e}_{y_1} + K_1^2 \int \hat{e}_{y_1} dt \\ \ddot{\hat{y}}_2^{ref} + K_2^1 \hat{e}_{y_2} + K_2^2 \int \hat{e}_{y_2} dt + K_2^3 \hat{e}_{y_2} \end{bmatrix}
$$
$$(30)$$

6. Simulation tests: comparison with experimental tests

Several experiments in presence of coupled driving/braking and steering maneuvers have been realized with an instrumented car. All trials are used to compute reference flat outputs and to deduce the blue curve of the race track depicted in Figure 11. For each trial, several dynamical parameters have been recorded at frequency $200\,Hz$; among them: longitudinal and lateral speeds, lateral and longitudinal accelerations, yaw and roll rates, wheel rotation speeds, longitudinal, lateral and vertical forces on four wheels, moments on four wheels, steering angle, etc. For simulations tests, two vehicle models are used: the first one is a NonLinear Two Wheels Vehicle Model
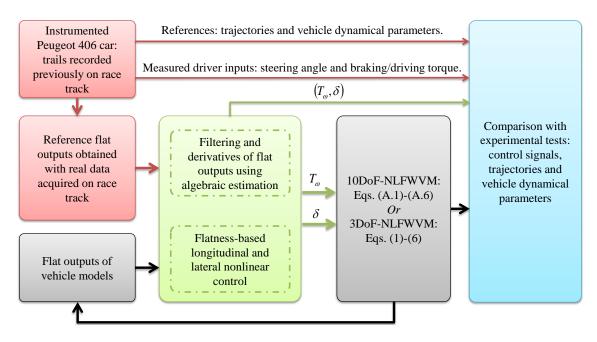

Figure 4: Validation diagram bloc: interaction between the algebraic estimation, vehicle models and flat nonlinear control

(1) (3DoF-NLTWVM), while the second is a full NonLinear Four Wheels Vehicle Model (A.1) (10DoF-NLFWVM).

Real data have been used firstly to generate the reference flat outputs, and secondly to compare them with the obtained results in closed-loop as shown in the validation scheme of Figure 4. More precisely, the blue curves of Figures 5-11 summarize the main measurements used for our validation. All measurements are recorded previously during a test conducted on a race track and employed for our simulations as reference signals. For all experiments, the professional driver has performed coupled maneuvers under high dynamical loads as highlighted by the blue curves of Figures 5-7. Moreover, we can observe that the coupled maneuvers like the steering control maneuver combined with accelerating action, and steering control maneuver combined with sudden and sharp braking action are performed.

Figures 5, 6 and 7 show that the obtained simulation results are close to the measurements such as yaw rate, longitudinal speed, longitudinal and lateral accelerations. Note also that the steering angle and braking/traction wheel torque provided by the combined control law are similar to the measured ones. These observations are valid for two vehicle models (3DoF or 10DoF) and for the coupled maneuvers as illustrated in Figure 5 between the positions from 600m to 750m and from 1000m to 1080m.

As mentioned previously, combined steering and braking maneuvers are simultaneously performed in the most dangerous curves of race track as depicted in Figures 8 and 11. The controller effectiveness in terms of tracking flat outputs errors are also depicted in Figures 9 and 10. Let us emphasize that the tracking errors are small and therefore the closed-loop behavior is quite satisfactory. Moreover, the tracking trajectory performance even under high dynamical loads with dangerous curves (lateral acceleration $-5\,m/s^2 \le a_y \le 5\,m/s^2$).

Through the simulation results, we can observe the ability

Figure 5: Control inputs: driving/braking torque control and steering angle

and the efficiency of the control law to produce an adequate behavior. Moreover, it is obvious that the behaviors of the controlled models are close to the real vehicle behavior. This observation is verified especially when the 10DoF vehicle model is coupled with the nonlinear flat controller. Indeed, as shown in Figure 8, the curvature of the controlled two wheels model is slightly different from the reference road curvature. In contrast, the performance in terms of the tracking trajectory is still satisfactory as shown in Figure 11 and for any given model.

The performance of the proposed controller for operating under extreme and coupled behaviors is also highlighted through
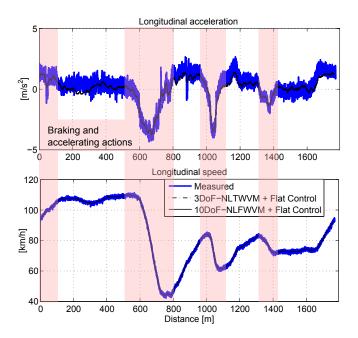

Figure 6: Longitudinal behavior of the controlled vehicle models and the actual one: longitudinal acceleration and longitudinal speed

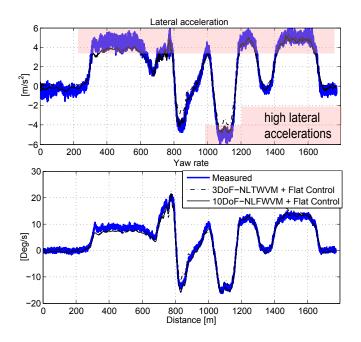

Figure 7: Lateral behavior of the controlled vehicle models and the actual one: lateral acceleration and yaw rate

Figure 8: Curvatures: reference and controlled vehicle model curvatures
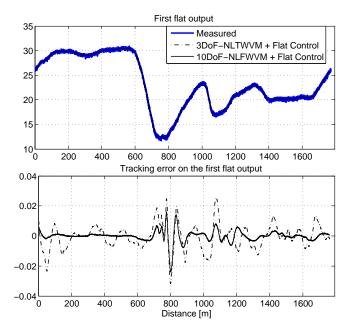

Figure 9: Tracking errors on the first output

the obtained results. On the other hand, the controller is able to operate with high values of lateral acceleration ($-5\,m/s^2 \leq a_y \leq 5\,m/s^2$) and longitudinal acceleration ($-5\,m/s^2 \leq a_x \leq 2\,m/s^2$), even in the presence of curved trajectories with a small radius of curvature ($20\,m < R < 35\,m$). It should be pointed out that the emergency situations, such as collisions and obstacle avoidance, lane-change maneuvers, can easily cause critical driving situations. For this reason, the performance of the control law are tested under high dynamics loads and coupled maneuvers.
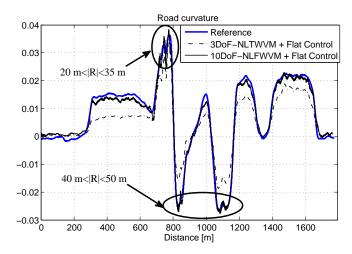

Remark 2. Let us emphasize that our results show that the performance of the control law is not affected by the model simplifications: neglected nonlinear terms $u_1 u_2$ and u_2^2 as shown by Figures 12, 13 and 14. It can be seen that the magnitude of these second order terms $u_1 u_2$ and u_2^2 is small: the maximum value is less than 0.8 for $u_1 u_2$ (Figure 12) and less than $2\,10^{-3}$ for u_2^2 (Figure 13).

Moreover, the flatness-based control still works in spite of parameter uncertainties as shown by Figure 15 where the coefficients C_f and C_r are 30% reduced. Similar robustness considerations apply to the time-delay problem. Let us point out that for these tests, 20 samples delay have been applied.

7. Conclusions

The proposed controller represents a promising solution for simultaneous control of longitudinal and lateral vehicle movements. To ensure the obtained results, a knowledge of nominal vehicle model is required. But, this knowledge is not guaranteed in the presence of fast dynamics like those induced by sudden changes of the road adherence and braking maneuvers leading to time-varying cornering stiffness coefficients. For this purpose, the recent work (Menhour et al., 2013) shows that, thanks to the new *model-free control* design (Fliess & Join, 2013),[4] some complex parameter identification might be avoided. It indicates possible simplifications for future works.

Appendix A. Nonlinear four wheels vehicle model equations

The motions of the Nonlinear four wheels vehicle model are governed by the following equations:

Dynamical model:
Longitudinal, lateral and vertical motions:
$$\begin{cases} m(\dot{V}_x + V_z\dot{\theta} - \dot{\psi}V_y) = m_s h\dot{\psi}\phi + \sum_{i=1}^{4} F_{xi} \\ \quad -F_{aero_x} + mg\sin(\phi_r - \theta_r) \\ m(\dot{V}_y + \dot{\psi}V_x - V_z\dot{\phi}) = -m_s h\ddot{\phi} + \sum_{i=1}^{4} F_{yi} \\ \quad -F_{aero_y} - mg\sin(\theta_r - \phi_r)\cos(\phi_r - \theta_r) \\ m(\dot{V}_z + V_y\dot{\phi} - V_x\dot{\theta}) = F_{z1} + F_{z2} + F_{z3} + F_{z4} - mg \end{cases}$$

Roll, pitch and yaw motions:
$$\begin{cases} (I_x + mh^2)\ddot{\phi} = -m_s h(\dot{V}_y + V_x\dot{\psi}) + I_{xz}\ddot{\psi} \\ \quad + [m_s gh - (K_{\phi f} + K_{\phi r})]\phi - (C_{\phi f} + C_{\phi r})\dot{\phi} \\ I_y\ddot{\theta} = (F_{z1} + F_{z2})L_1 + (F_{z3} + F_{z4})L_2 - \sum_{i=1}^{4} h_i F_{xi} \\ \quad + (I_z - I_x)\dot{\psi}\dot{\phi} \\ I_z\ddot{\psi} - I_{xz}\ddot{\phi} = M_{z1} + M_{z2} + M_{z3} + M_{z4} + \sum_{i=1}^{4} C_{zi} \end{cases} \quad \text{(A.1)}$$

Wheels rotation motions:
$$\begin{cases} I_\omega\dot{\omega}_1 = -RF_{x\omega 1} + T_{\omega 1} \\ I_\omega\dot{\omega}_2 = -RF_{x\omega 2} + T_{\omega 2} \\ I_\omega\dot{\omega}_3 = -RF_{x\omega 3} + T_{\omega 3} \\ I_\omega\dot{\omega}_4 = -RF_{x\omega 4} + T_{\omega 4} \end{cases}$$

kinematics model:
$$\begin{cases} \dot{x} = V_x\cos\psi - V_y\sin\psi \\ \dot{y} = V_x\sin\psi + V_y\cos\psi \end{cases} \quad \text{(A.2)}$$

It should be pointed out that the above nonlinear vehicle model expresses the coupling of kinematics, dynamics and tyre which are described in Remark 1.
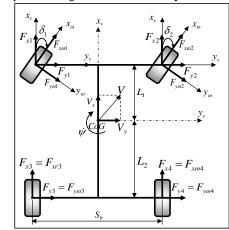

Appendix A.1. Tyre model

To obtain a realistic representation of the vehicle behavior and simulate the limit handling situations where the extreme driving situations are present, the coupled nonlinear tyre model of Pacejka (Pacejka, 2006) is used. In this model, the coupling of vertical, longitudinal and lateral motions are taken into account. The following illustrative equations can be used as general expressions for longitudinal and lateral tyre forces:
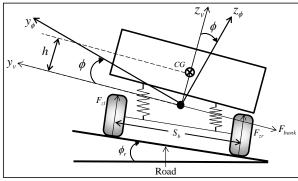

$$\begin{cases} F_{x\omega i} = f_x(\zeta_i, \lambda_i, \alpha_i, F_{zi}) \text{ for } i = 1, \cdots, 4 \\ F_{y\omega i} = f_y(\zeta_i, \lambda_i, \alpha_i, F_{zi}) \text{ for } i = 1, \cdots, 4 \end{cases} \quad \text{(A.3)}$$

For different loads, the relationships between lateral tire force and slip angle are given in Figure A.17. These forces are linear for small sideslip angles with constant cornering stiffness coefficients (C_f and C_r) (see Figure A.17). When the slip angle increases, the lateral tire force behavior becomes nonlinear. These changes are described by transition and saturation regions.

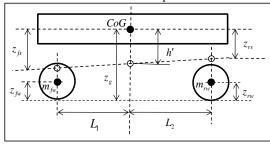

Figure A.16: Nonlinear four wheels vehicle model with roll and pitch motions

In Eq. (A.1), the longitudinal and lateral forces acting on each wheel in the vehicle coordinate system F_{xi} and F_{yi}, are related to the tyre forces along the wheel axes, $F_{x\omega i}$ and $F_{y\omega i}$ as follows:

$$\begin{pmatrix} F_{xi} \\ F_{yi} \end{pmatrix} = \begin{pmatrix} \cos\delta_i & -\sin\delta_i \\ \sin\delta_i & \cos\delta_i \end{pmatrix} \begin{pmatrix} F_{x\omega i} \\ F_{y\omega i} \end{pmatrix} \quad \text{(A.4)}$$

In this model, the coupling of longitudinal slip ratio λ_i, sideslip α_i, vertical forces F_{zi} and camber angle ζ_i are taken into account.

Appendix A.2. Vertical forces

In static situations, the vertical forces are due to the gravitation. During the driving situations the vehicle is subject to transfer loads caused by a coupled motion such as longitudinal acceleration, braking action, cornering situations, roll motion,
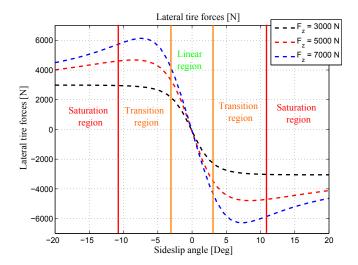

Figure A.17: Pacejka's Model, lateral force for different load and sideslip angle

lateral acceleration, geometry of the road (slope and road bank angles), consequently the vertical forces can be expressed as follows:

$$
\begin{cases}
F_{z1} = \frac{L_2 mg \cos\phi_r \cos\theta_r}{2(L_2+L_1)} - \frac{hma_x}{2(L_2+L_1)} - \frac{L_2 hma_y}{S_b(L_2+L_1)} \\
\qquad - \frac{\left(K_{\phi f}\phi + C_{\phi f}\dot{\phi}\right)}{S_b} \\
F_{z2} = \frac{L_2 mg \cos\phi_r \cos\theta_r}{2(L_2+L_1)} - \frac{hma_x}{2(L_2+L_1)} + \frac{L_2 hma_y}{S_b(L_2+L_1)} \\
\qquad + \frac{\left(K_{\phi f}\phi + C_{\phi f}\dot{\phi}\right)}{S_b} \\
F_{z3} = \frac{L_1 mg \cos\phi_r \cos\theta_r}{2(L_2+L_1)} + \frac{hma_x}{2(L_2+L_1)} - \frac{L_1 hma_y}{S_b(L_2+L_1)} \\
\qquad - \frac{\left(K_{\phi r}\phi + C_{\phi r}\dot{\phi}\right)}{S_b} \\
F_{z4} = \frac{L_1 mg \cos\phi_r \cos\theta_r}{2(L_2+L_1)} + \frac{hma_x}{2(L_2+L_1)} + \frac{L_1 hma_y}{S_b(L_2+L_1)} \\
\qquad + \frac{\left(K_{\phi r}\phi + C_{\phi r}\dot{\phi}\right)}{S_b}
\end{cases}
\tag{A.5}
$$

It should be noted that the load transfer due to the pitch and the suspension motions are not considered. These equations can be easily obtained using the torque balance construction, an example of the calculation of the vertical forces based on this approach is presented in (Kiencke & Nielsen, 2004).

Appendix A.3. Sideslip angles

The nonlinear equations of tire slip angles are:

$$
\begin{cases}
\alpha_1 = \delta - \arctan\left(\frac{V_y + L_1\dot{\psi}}{V_x - \frac{S_b}{2}\dot{\psi}}\right) \\
\alpha_2 = \delta - \arctan\left(\frac{V_y + L_1\dot{\psi}}{V_x + \frac{S_b}{2}\dot{\psi}}\right) \\
\alpha_3 = -\arctan\left(\frac{V_y - L_2\dot{\psi}}{V_x - \frac{S_b}{2}\dot{\psi}}\right) \\
\alpha_4 = -\arctan\left(\frac{V_y - L_2\dot{\psi}}{V_x + \frac{S_b}{2}\dot{\psi}}\right)
\end{cases}
\tag{A.6}
$$

Table A.1: Notations (part I)

Symbol	Variable name
α_i	tyre slip angle $[rad]$
β	sideslip angle at CoG $[rad]$
δ	wheel steer angle $[rad]$
λ_i	longitudinal slip ratio
ϕ, $\dot{\phi}$	roll angle $[rad]$, roll rate $[rad/s]$
ϕ_r	road bank angle $[rad]$
